

DORIS station equipment / impact on the frequency

The DORIS Network is composed of **about 60 ground stations**.

Among these, most are defined as **Orbitography Beacons (BO)** which will be used as geographic references by orbit determination software.

Some of these Orbitography Beacons also play the role of **Time Beacons (BT)**. The Time-Beacon clocks are linked to atomic clocks. Clocks delays are precisely determined and monitored with respect to the International Atomic Time (TAI).

Some BTs are also **Master Beacons (BM)**: they also emit broadcast uploads.

1/ Orbitography Beacons (BO): There is a USO inside the beacon → the change of the beacon may lead to a frequency change.

2/ Master Beacons (BM): No USO in a master beacon, it is in the tracking Oscillator (itself fed by a 5 MHz external clock, a cesium for the long-term stability). → so the frequency change may occur when we change the tracking oscillator or the external clock (not when the beacon is changes).

3/ Time beacons (BT): No USO inside a time beacon, the beacon is linked to an external clock (Maser or equivalent) → an event on the external clock may have an impact on the frequency, not a beacon change.
